Received December 10, 2009

Theoretical analyses are presented on the critically phase-matched second-harmonic generation (SHG) in a biaxial crystal with the focused fundamental Gaussian beams. The dependence of the second-harmonic light power on the phase matching conditions, focused geometries, walk-off effects, and absorptions are discussed in detail. Expressions are presented for calculating the light power of the types I and II SHGs in the biaxial crystal, applied to optimize the blue light generation with the LiB₃O₅ crystal. A maximum conversion efficiency of around 37% is obtained with 798-nm laser power of 500 mW.

OCIS codes: 190.2620, 140.3515, 160.4330, 140.3560.

doi: 10.3788/COL20100807.0693.
where $a_2$ is the absorption coefficient for the SH light in the crystal, $d$ is the effective nonlinear coefficient, $a = a_1 - a_2$, and $\tau' = 2(\tau - f)/b$.

The intensity of the SH light in the far field ($\tau' \to \infty$) outside the crystal is

$$I = \frac{1}{2} \varepsilon_0 c n_2 |E_{2\omega}|^2 = \frac{8 P^2 d^2 \omega^3 k^2_1}{\varepsilon_0 c n_2^2 n_2^2} \exp(\text{a}lu) \times \exp(-a'l) \times \exp[-4(s^2 + s'^2)] |H|^2,$$

(3)

where $s = x_1/(w_0 \tau'), s' = [y_1 - \rho_2 x_2(l - f)]/(w_0 \tau'), a' = a_1 + a_2/2$, the focal position is $\mu = (l - 2f)/l$, and

$$H = \frac{1}{2 \pi} \int_{(1+\mu)}^{(1-\mu)} \exp(-\kappa \tau + i\sigma' \tau') \frac{1}{1 + i \tau} d\tau.$$

(4)

In the above, $\sigma' = \sigma - 4(\beta_1 - \beta_2) s'$, the phase mismatching parameter $\sigma$ is defined as $\sigma = b_2 k/2$, the focusing parameter $\xi$ is defined as $\xi = l/b$, and $\kappa = ab^2/2$.

By integrating the SHG intensity, the SH light power can be written as

$$P_{2\omega} = \frac{2P^2 d^2 \omega^3}{\varepsilon_0 c n_2^2 n_2^2} k_1 l \exp(-a'l) \times h(\sigma, B, \kappa, \xi, \mu),$$

(5)

where the BK factor is

$$h(\sigma, B, \kappa, \xi, \mu) = \frac{1}{4\xi} \exp(\text{a}lu) \int_{(1+\mu)}^{(1-\mu)} \exp[-\kappa (\tau + \tau') + i\sigma(\tau' - \tau) - B^2(\tau' - \tau)^2/\xi] \frac{1}{1 + i \tau} d\tau,$$

(6)

In the above, $B^2 = B_1^2 + B_2^2$. The double-refraction parameter $B_1 (B_2)$ is defined as $B_1 = \rho_2 x_2(ik_1)^{1/2}/2$ ($B_2 = \rho_2 x_2(ik_1)^{1/2}/2$). The double refraction parameter $B$ in the type I SHG consists of two terms ($B_1, B_2$) because two extraordinary axes exist in the biaxial crystal, and, in contrast, just one extraordinary axis exists in the uniaxial crystal, as shown in Eq. (5). For type I SHG in a negative (positive) uniaxial crystal, in which the double-refraction parameter $B = B_2$ ($B = B_1$), the result agrees with that presented in Ref. [7].

According to the phase-matching theory, fundamental waves are formed by orthogonally polarized lights ($E_{\omega}$ and $E_{\omega}'$) in type II SHG. The configuration of the type II SHG in the biaxial crystal can be generalized and are presented in Fig. 2[12]. The beam propagation directions are along the $z$ axis. The double refraction directions for the fundamental waves are $dx/dz = tan \rho_1 \approx \rho_1$ and $dy/dz = tan \rho_2 \approx \rho_2$. For the SHG wave, it is $dy/dz = tan \rho_2 = \rho_2$.

In type II SHG, the fundamental electric field is composed of two orthogonally polarized components ($E_{\omega}, E_{\omega}'$). In Fig. 2, the fundamental electric fields ($E_{\omega}, E_{\omega}'$) in the crystal can be expressed as

$$E_{\omega}(x, y, z) = E_{0}(1 + i \tau)^{-1} \exp(ikz - i\omega_1 t) \times \exp \left\{ \frac{[x - \rho_1(z - f)]^2 + y^2}{w_0^2(1 + i \tau)} \right\} \times \exp \left\{ \frac{-1}{2} a_1 z \right\},$$

(7a)

and

$$E_{\omega}'(x, y, z) = E_{0}(1 + i \tau)^{-1} \exp(ikz - i\omega_1 t) \times \exp \left\{ \frac{-x^2 + [y + \rho_2(z - f)]^2}{w_0^2(1 + i \tau)} \right\} \times \exp \left\{ \frac{-1}{2} a_1 z \right\},$$

(7b)

Then, the electric field of the SH light at the observer point $P(x_1, y_1, z_1)$ in type II SHG is calculated. As the two fundamental fields have different polarizations, we assume two source points ($R_1, R_2$) as shown in Fig. 2. At the same time, the walk-offs of the fundamental fields have been taken into account in Eq. (7). Therefore, the observer point $P(x_1, y_1, z_1)$ and the source points $R_1(x, y, z)$ and $R_2(x, y, z)$ satisfy $y = y_1 - \rho_{2\omega}(z_1 - z), (z_1 < l)$; $y = y_1 - \rho_{2\omega}(l - z), (z_1 > l)$; $x = x_1, (0 \leq z \leq l)$. The electric field of the SH light outside the crystal is

$$E_{2\omega}(x_1, y_1, z_1) = \frac{\varepsilon_1 d E_{\omega}^2}{\varepsilon_0 c n_2^2(1 + i \tau')} \times \exp(-a_2l/2 + 2ik_1z_1 - 2i\omega_1 t) \times \int_{0}^{l} dz \exp(-az + i\Delta kz) \frac{1}{1 + i \tau} \exp \left\{ \frac{[x_1 - \rho_1(z - f)]^2 + [y_1 - \rho_{2\omega}(l - z)]^2 + x_1^2 + [y_1 - \rho_{2\omega}(l - z) + \rho_2(z - f)]^2}{w_0^2(1 + i \tau')} \right\},$$

(8)

Therefore, the SH power in the far field ($\tau' \to \infty$) outside the crystal is

$$P_{2\omega} = \frac{2P^2 d^2 \omega^3}{\varepsilon_0 c n_2^2 n_2^2} k_1 l \exp(-a'l) \times h(\sigma, B, \kappa, \xi, \mu).$$

(9)

Here, $B^2 = B_1^2 + B_2^2+B_3+B_1^2/4+B_2^2/4$. The double refraction parameters are defined as $B_1 = \rho_1(ik_1)^{1/2}/2$, $B_2 = \rho_2(ik_1)^{1/2}/2$, and $B_3 = \rho_2(ik_1)^{1/2}/2$. As can be seen from Eq. (9), the double-refraction parameter $B$ in the type II SHG is more complicated than that in the type I SHG. The difference is caused by the different double refraction directions of the orthogonally polarized fundamental waves in type II SHG.

To realize Yb lattice clock, it is essential that 399 nm
Fig. 1. Type I phase-matched SHG in a biaxial crystal in laboratory coordinates (x, y, and z). \( s_0 \) (\( s_{2\omega} \)) is the energy flow direction of the fundamental (SH) wave, \( \rho_0 \) (\( \rho_{2\omega} \)) is the walk-off angle of the fundamental (SH) wave, \( R \) (\( P \)) is the source (observer) point, \( k_1 \) is the propagation direction of the fundamental light, and \( f \) is the focus of the fundamental Gaussian beam.

$^{1}$S\(_0\)→P\(_1\) broad line transition is used to cool and trap Yb atoms$^{[15-17]}$. The PPKTP and LBO crystals are the possible candidates for generating a 399-nm laser. Villa et al. have achieved high-efficient blue light generation with PPKTP$^{[16]}$; however, thermal lensing and bistability appeared in the experiment when the fundamental power surpassed 300 mW. The LBO widely used for blue and green light generation is a typical biaxial crystal. Compared with the PPKTP crystal, it has higher optical homogeneity, higher damage threshold, and broader transparency range resulting in low loss for both the 399- and 798-nm laser lights. Therefore, we adopted frequency doubling of a diode laser using the LBO crystal to generate light source at 399 nm. To minimize surface losses, Brewster-cut LBO crystal was used in the design because of the following advantages: minimum residual reflections on both facets, larger damage threshold, and longer lifetime compared with the anti-reflection (AR) coated LBO crystal$^{[18]}$. In the following, we applied the theory to analyze blue 399-nm light generation in a biaxial crystal. The calculations were performed for a 3×3×12 (mm) crystal.

SHG is the most efficient when it is phase matched. According to the refractive indices in Table 1, the maximum nonlinearity can be achieved at type I phase matching with \( \theta=90^\circ \) and \( \varphi \approx 31.9\text{mrad}^{[10,11]} \), where \( \theta \) is the angle between the wave propagation direction and Z axis, and \( \varphi \) is the angle between the projection of wave propagation direction in X-Y plane and X axis.

After phase matching, the refractive indices of both fundamental and SH lights are 1.611, hence obtaining a Brewster angle of \( \varphi=58.17^\circ \). The magnitudes of walk-off angles are shown in Table 2, and the details of the calculation can be found in Ref. [12]. We will use Eq. (5) for type I phase-matched SHG in a biaxial crystal in the following optimizations and calculations.

With the data shown in Table 2, the BK factor in Eq. (5) can be plotted in Fig. 3. We find that the maximum value of \( h(\xi) \) is 0.101 at \( \xi \sim 1.5 \), indicating that the optimal beam waist of the fundamental beam is around 25 µm. Given the small nonlinearity of the LBO crystal, we chose to enhance the fundamental field in a four-mirror ring cavity. Compared with a semi-monolithic resonator, this configuration can avoid feedback to the laser diode and manifests low loss$^{[18]}$.

Figure 4 shows that the M1 and M2 cavities are flat mirrors, and that M3 and M4 are concave mirrors with the same radius of curvature of \( R_c \). Here, M1 is the input coupler, M4 is the output coupler, and the length of the crystal is \( l \). The cavity can be analyzed in terms of \( ABCD \) matrix method$^{[19]}$. The radius of curvatures of the two concave mirrors was chosen as \( R_c=70 \) mm. Given that the angle-tuned phase matching and the Brewster-cut surfaces in the design can cause astigmatism$^{[9,18]}$, we compensated for this by making the folding angle \( \theta \) (as formed by the light ray and the surface normal of the concave mirror), thereby satisfying the relation \( R_c \tan \theta \sin \theta = l/(n^2-1)/n^3$[18], where \( n \) is the refractive index, and \( \theta=14.5^7^\circ \).

From the theory of Ashkin et al.$^{[20]}$, we learned that the largest SHG conversion efficiency can be obtained when the cavity is impedance matched. Mirrors M2, M3, and
achieved a maximum BK factor with the required waist inside the crystal and ABCD Eq. (11); through the conversion efficiency the impedance matched cavity impedance matching condition, the optimal reflectivity and the crystal loss at fundamental wavelength is around input fundamental light power; the SHG in a typical biaxial crystal in the form of a LBO in biaxial nonlinear crystals. As an example, we optimize practical guidance for determining the optimum operating condition and estimation of SHG conversion efficiency on these parameters. Such an analysis provides a theoretical and estimation of SHG conversion efficiency of two effects are analyzed. As a result, the dependence of SHG power in the biaxial crystal on these parameters is clarified. Such an analysis provides a theoretical and polars of laser beams, and corresponding walk-off effects are analyzed. As a result, the dependence of SHG power in the biaxial crystal on these parameters is clarified. Such an analysis provides a theoretical and walk-off effects are analyzed. As a result, the dependence of SHG power in the biaxial crystal on these parameters is clarified. Such an analysis provides a theoretical and references.

M4 were selected with a high reflectivity of 99.97% for the fundamental light, and M4 has a transmission coefficient of up to 94% for the SH light. Generally, the absorption at 798 nm is estimated to be $a_1 \sim 0.31%$/cm, the absorption at 399 nm is estimated to be $a_2 < 0.1%$/cm$^{[21]}$, and the crystal loss at fundamental wavelength is around 0.45%$^{[5]}$. As the output facet of the LBO crystal is Brewster-cut for 798 nm, the transmissivity of the crystal for 399 nm, $\tau_0$, is around 80.3%$^{[22]}$. To achieve the impedance matching condition, the optimal reflectivity $r_m$ of M1 is around 99.4%; the ratio of the light power in the impedance matched cavity $P_{cm}$ to the incident light power $P_1$ can be represented as$^{[20]}$

$$\frac{P_{cm}}{P_1} = \frac{1}{1 - r_m}.$$  \hspace{1cm} (10)

Substituting $P_{cm}$ into Eq. (5), the SHG output power outside the resonant cavity $P_{SHG}$ becomes

$$P_{SHG} = KP_{cm}^2 k_1 \exp(-a'f) \cdot h(\kappa, \sigma, B, \xi) t_2 t_4 \tau_0.$$  \hspace{1cm} (11)

where $t_2$ is the transmission coefficient of the output coupler and $K = 2\omega_0^2 d^2 / (\varepsilon_0 c n_1 n_2 \pi)$. We defined the SHG conversion efficiency $\eta$ as $\eta = P_{SHG} / P_1$.

The SHG conversion efficiency can be estimated from Eq. (11); through the $ABCD$ matrix, we designed a resonator with the required waist inside the crystal and achieved a maximum BK factor $h(\xi) = 0.101$. In the calculation, the fundamental light power $P_1$ refers to the light power which is mode-matched into the cavity. Substituting all the parameters into Eq. (11), blue light generation of 188 mW at 399 nm could be generated with 500-mW mode-matched light power at 798 nm, and is equal to a conversion efficiency of around 37%.

In conclusion, we present a theoretical analysis for both types I and II phase-matched SHGs in a biaxial nonlinear crystal. Specific phase-matching conditions, polarizations of laser beams, and corresponding walk-off effects are analyzed. As a result, the dependence of SHG power in the biaxial crystal on these parameters is clarified. Such an analysis provides a theoretical and practical guidance for determining the optimum operating condition and estimation of SHG conversion efficiency in biaxial nonlinear crystals. As an example, we optimize the SHG in a typical biaxial crystal in the form of a LBO crystal. A 188-mW laser light emission at 399 nm could be efficiently generated with 500-mW mode-matched fundamental light power, suitable for cooling and trapping Yb atoms.
