A novel temperature sensor based on a dual-core fiber (DCF) is proposed and theoretically analyzed. The DCF-based temperature sensor is simply formed by splicing a segment of DCF to two segments of single mode fibers, where the DCF is used as the sensing element. The mode coupling between two fiber cores of the DCF is sensitive to the temperature-induced index change of the silica in the DCF. Simulations show that there is a linear relationship between the temperature of the DCF and the wavelength shift of the output spectrum of the DCF-based temperature sensor when the broadband light is injected into one fiber core of the DCF. Temperature sensors based on DCFs with different parameters for temperature sensing are also investigated.

Optical fiber sensors have attracted considerable attention in the past three decades due to their advantages such as small size, light weight, high sensitivity, multiplexing capability, immunity to electromagnetic interference, and so on\textsuperscript{[1–9]}. Among them, temperature sensors based on optical fiber devices using various techniques such as Raman and Brillouin scattering\textsuperscript{[6–9]}, fiber Bragg grating (FBG)\textsuperscript{[10–12]}, long-period fiber grating (LPG)\textsuperscript{[13,14]}, and interferometry\textsuperscript{[15–18]} have been extensively investigated due to their broad applications in fundamental research, electrical power engineering, astronomical engineering, energy and power engineering, and chemical industry. Temperature sensors based on the Raman/Brillouin scattering have successfully achieved distributed temperature measurement but suffer from the limited measurement range (less than 100 °C). FBG and LPG are two of the most particular temperature fiber sensors because of its capability of multiplexing. However, we need costly fabrication system for the FBG (LPG) and the operational temperature of the FBG (LPG) fabricated using UV laser writing is usually very low (e.g., 300 °C for the FBG written into the B- and Ge-codoped silicate fiber) due to the poor thermal stability of the UV-induced refractive index change\textsuperscript{[19]}. Special materials or fabrication processing are needed for high-temperature FBG sensors\textsuperscript{[20–23]}. Temperature sensors based on Fabry–Perot interferometer\textsuperscript{[24–26]} and modal interferometer\textsuperscript{[27,28]} have successfully achieved high-temperature sensing, among which special fibers such as the photonic crystal fiber and multimode fiber (MMF) have been used for high-temperature sensing.

In this letter, we propose a kind of novel temperature sensor based on a dual-core fiber (DCF) with an operational principle of the mode coupling between two fiber cores (formed two individual waveguides). The DCF-based temperature sensor is simply formed by splicing a segment of DCF to two segments of single mode fibers (SMFs). Temperature information is achieved by measuring the wavelength shift of the output spectrum of the DCF-based temperature sensor. The proposed DCF-based temperature sensor can be used for high-temperature (> 1000 °C) sensing with a sensitivity of about 7 pm/°C.

Figure 1(a) shows the cross-section of the proposed DCF. Two fiber cores (α and β) with the diameter (d) and the center-to-center distance (H) are arranged symmetrically in the cross-section of the DCF. The outside diameter of the DCF is D, which is fixed to be 125 μm to match the SMF. To simplify analysis, the refractive index of the silica under the reference temperature \(T = 0\,°C\) is assumed to be 1.45 and the refractive index difference between the fiber core and fiber cladding is δ, which is 0.32%, 0.36%, and 0.40% for different DCFs in our calculations, respectively. Figure 1(b)
shows the structure of the temperature sensor based on
the proposed DCF. A segment of the proposed DCF with a
length \( L \) is spliced to SMF1 by matching fiber core \( \alpha \) to
the fiber core of SMF1 on one side and to SMF2 by
matching fiber core \( \beta \) to the fiber core of SMF2 on
another side, which results in an offset between the DCF
and the SMF on both sides. The broadband light is in-
jected to the fiber core \( \alpha \) through SMF1 and we detect
the signal on the output side of the fiber core \( \beta \) through
SMF2.

The operational principle of the temperature sensor is
based on the thermo-optic effect and the mode coupling
of the DCF. The thermo-optic coefficient of the silica is
\( dn/dT = 10^{-5}/^\circ\text{C} \), and we have the refractive index
of the silica under the temperature \( T \)
\[
n = 1.45 + T \times 10^{-5},
\]
which indicates the effective index of the DCF depends
on the temperature \( T \). The mode coupling of the two
fiber cores in the DCF is briefly introduced as follows.
Suppose that the powers of the injected light on the
input side of the fiber core \( \alpha \) (SMF1) and the fiber core \( \beta \)
are 1 and 0, respectively. According to the conventional
coupled-mode theory \(^{30}\), the output power on the output
side of the fiber core \( \alpha \) and the fiber core \( \beta \) (SMF2) of
the DCF with a length \( L \) can be given by
\[
P_1(L) = \cos^2(SL) + \cos^2(\eta)\sin^2(SL),
\]
\[
P_2(L) = \sin^2(\eta)\sin^2(SL),
\]
where the later one is the output power of the DCF-based
temperature sensor. Note that we have
\[
S = |n_e - n_o|\pi/\lambda, \\
S = \sqrt{\delta^2 + \kappa^2}, \\
\tan(\eta) = \kappa/\delta, \\
\delta = |n_a - n_b|\pi/\lambda, \\
\]
where \( \lambda \), \( n_e(n_o) \), and \( n_a(n_b) \) are the operational wave-
length, the effective index of the even (odd) mode of two
fiber cores, and the effective index of individual fiber
core \( \alpha (\beta) \). For the DCF, we have \( \delta = 0 \) when the
fiber core \( \alpha \) and the fiber core \( \beta \) are symmetrical in the DCF.
Thus, Eqs. (2) and (3) can be rewritten as
\[
P_1(L) = \cos^2(SL),
\]
\[
P_2(L) = \sin^2(SL).
\]
Let \( \Delta n_{eo} = |n_e - n_o| \), which is dependent on both the
operational wavelength and the temperature. Then the
output power of the DCF-based temperature sensor is
\[
P_2(T, \lambda) = \sin^2(|n_e - n_o|\pi L/\lambda) = \sin^2[\Delta n_{eo}(T, \lambda)\pi L/\lambda],
\]
where we can achieve temperature information by mea-
suring the output spectrum of the DCF-based temperature
sensor due to \( P_2(T, \lambda) \).

The proposed DCF has two basic modes with the
effective index \( n_e \) for the even mode and the effective
index \( n_o \) for the odd mode. A well-known finite-
element method (FEM) \(^{31}\) which can calculate the
effective index and mode profile is used to investigate the
guiding modes of the DCF. Figure 2 shows the normal-
ized electric field distribution along the radial direction
for the even mode and the odd mode of the DCF with
parameters of \( H = 12 \mu\text{m} \), \( d = 8.2 \mu\text{m} \), and \( \delta = 0.36\% \).
The operational wavelength is \( \lambda = 1550 \text{ nm} \) and the DCF
is under the reference temperature \( T = 0 \text{ °C} \). Insets show
the corresponding mode profiles of the electric field.

For the DCF under different temperatures, the FEM
is used to calculate the effective indices of the even
mode and the odd mode and different output spectra
is achieved based on Eq. (7). Figure 4(a) shows the
output spectra of the DCF-based temperature sensor
when the 10-cm DCF is under temperatures 0, 200, 400,
600, 800, and 1 000 °C, respectively. We can find that
the output spectrum shifts to the longer wavelength

\begin{figure}
\centering
\includegraphics[width=\textwidth]{image.png}
\caption{Normalized electric field distribution along the radial direction for (a) the even mode and (b) the odd mode of the DCF with parameters of \( H = 12 \mu\text{m} \), \( d = 8.2 \mu\text{m} \), and \( \delta = 0.36\% \). Insets show the corresponding mode profiles of the electric field.}
\end{figure}

\begin{figure}
\centering
\includegraphics[width=\textwidth]{image.png}
\caption{(a) \( \Delta n_{eo} \) versus wavelength in the range from 1 540 to
1 560 nm and (b) output spectrum of the temperature sensor
based on 10 cm (dotted curve) or 15 cm (solid curve) DCF.}
\end{figure}
when the temperature increases, which is due to the decreased value of $\Delta n_m$ for high temperature. The sensitivity of the DCF-based temperature sensor is about 0.0072 nm/°C. Figure 4(b) shows the valley wavelength (around 1550 nm) of the output spectrum of the DCF-based temperature sensor for different temperatures. It can be seen that there is a linear relationship between the valley wavelength and the temperature.

Figure 5 shows the wavelength shift of the output spectrum of the temperature sensor based on DCFs with different parameters: $(H = 12 \mu m, d = 8.2 \mu m, \delta = 0.36\%)$, $(H = 13 \mu m, d = 8.2 \mu m, \delta = 0.36\%)$, $(H = 11 \mu m, d = 8.2 \mu m, \delta = 0.36\%)$, $(H = 12 \mu m, d = 9.0 \mu m, \delta = 0.36\%)$, $(H = 12 \mu m, d = 7.4 \mu m, \delta = 0.36\%)$, $(H = 12 \mu m, d = 8.2 \mu m, \delta = 0.40\%)$, and $(H = 12 \mu m, d = 8.2 \mu m, \delta = 0.32\%)$. Note that all DCFs have the same length of 10 cm. Inset of Fig. 5 shows a partial enlarged view for the temperature sensors based on DCFs with different parameters. (600, 800, and 1000°) can be seen that there is a linear relationship between the temperature and the wavelength shift for the same temperature. Considering all DCFs have the same length of 10 cm. Inset of Fig. 5 shows a partial enlarged view for the temperature sensors based on DCFs with different parameters.
